The Problem of Digital Dating: A Model for Uncertainty in Medieval Documents

Peter A. Stokes  Department of Digital Humanities, King’s College London

The dates of medieval documents are often not precisely known and so are catalogued with labels such as ‘early twelfth century’. While these labels are useful and meaningful for a medievalist, they present difficulties in a digital context in terms of searching, sorting, and aggregating existing descriptions. This paper will examine these challenges, propose an alternative way of modelling dates, and then make some suggestions for representing these in user interfaces. It draws on work for Models of Authority, a new project on Scottish charters of the twelfth century which is funded by the UK Arts and Humanities Research Council and which uses and extends the DigiPal framework (DigiPal 2010–14).

The Problem

Scholars have developed conventions for recording the various degrees of uncertainty in dates of manuscripts and documents. To take an example from Models of Authority: National Library of Scotland GD55/32 was written between 1189 and 1196; by convention this is indicated ‘1189×1196’ (POMS document no. 3/14/3). However, one or both dates in this range may be approximate or uncertain (‘circa 1192 × 24 March 1201’: POMS 3/486/8), or different date ranges may be possible (‘A.D. 670 × 671 [? A.D. 681]’: eSawyer S.1168). Alternatively, only a general date might be known (‘late twelfth/early thirteenth century’: POMS no. 3/590/9). Other possibilities include ‘early’, ‘mid’, or ‘late’ in the twelfth century; the first or second half of the century; and sometimes the second quarter, the first third, and so on (see further examples in DigiPal 2010–14 and eSawyer 2010, as well as DigiPal, ‘Glossary’).

This system of dating has served medievalists well. However, there is no obvious way of searching for or ordering material labelled in this way. When exactly does ‘late twelfth century’ begin and end? Does it include the last quarter of the century? Does the first quarter of the twelfth century come before or after the ‘early' twelfth century? Where does ‘A.D. 670 × 671 [? A.D. 681]’ fit on a timeline? We can decide answers to all of these questions in any given application, as indeed has been done (Stokes 2012; see also the ‘search by date’ function in Manuscripts Online, and DigiPal’s faceted search, among many others). However, the result will necessarily be arbitrary and therefore difficult for others to understand. It will also inevitably be inconsistent with practice in other projects, and this in turn will lead to problems with linked data or aggregating sites (examples of which in this context include Biblissima, MESA and Manuscripts Online). One could try to recover the intentions of the original cataloguer(s) but this is often lost and, even if recoverable, is unlikely to be consistent from one source to the next. Models of uncertainty do exist which go some way towards capturing these formulae, such as that in the TEI Guidelines (§§13.1.2 and 21.2), but they

1 This section of the proposal draws extensively from Stokes 2012.
still leave open these problems of searching and presenting the material. Instead, an alternative is required.

**The Model**

It is argued here that to ask if ‘early twelfth century’ includes the year 1100 is legitimate in a digital context, but to medievalists is in many ways a meaningless question, since if cataloguers knew that the manuscript was written after 1100 then they would have specified this. ‘Early twelfth century’ does not mean ‘no earlier than midnight 1 January 1100 and no later than midnight 31 December 1115’, but rather something closer to ‘probably some time in the first fifteen years or so of the century, but perhaps a little later or earlier’. To indicate this difference more concretely, it is useful to use probability density functions. Summarising crudely, a probability density function (pdf) represents the likelihood that a given variable has a given value. For instance, if we know when a document was written then it has 100% probability of being written then and zero of being written any other point of time; the resulting pdf is the Dirac delta function and is conventionally represented as shown in Figure 1. The assumption implicit in many search interfaces that ‘early twelfth century’ has a fixed and firm beginning and end, say 1100×1115, can be represented using the rectangular distribution shown in Figure 2. In contrast, judging intuitively from my own experience with manuscripts, ‘early twelfth century’ is probably captured more accurately by something like a normal distribution (Figure 3). We can also combine these for more complex cases like ‘A.D. 670 × 671 [? A.D. 681]’ (Figure 4). Indeed the range of possible curves is essentially limitless, and the model is sufficiently general to allow for any curve that best represents the particular case at hand.

Figure 2 Rectangular distribution representing ‘1100×1115’

Figure 3 Normal distribution representing ‘early twelfth century’
It is important to emphasise that these curves do not necessarily represent the mathematical likelihood of the date of writing, or even of the cataloguer’s judgment, since accurately quantifying human impressions is difficult and problematic. Indeed, the resulting curves need not even necessarily be true pdf's. They may be mathematically valid and numerically accurate in a given implementation, but this assumes a reliable statistical model and so seems only appropriate for those projects which are sufficiently quantitative that such a model is available (examples may include DEEDS and work described by Smit 2011 or Wolf 2015). However, it would be incumbent on people using this approach to demonstrate the validity of their statistical representation (for cautions against which see Sculley and Pasanek 2008; Stokes 2009; Hassner 2013). The point is in fact the opposite: rather than providing exact figures, they are intended instead to represent more meaningfully in digital form when the scholar in question considered the document to have been written. For instance, if I want to communicate the approximate frequency of a given letter-form in time, then instead of using a simple timeline like that shown above, I can instead calculate the sum of the distribution functions of all the scribal hands that show this form. Figure 5 shows the resulting curve for all occurrences in the DigiPal database of the tall-e form of the letter æ, and this seems to effectively capture the received view that the letter-form was common early in the eleventh century but went out of use soon after (Ker 1957; Stokes 2014). Alternative representations could include lines of varying colour, adjusting the value or saturation according to the value and thereby allowing easier comparison of different categories, or perhaps even transparency, where users adjust the date and, according to their distribution, images of the relevant letters fade in and out of view. The curves could also be used to provide a significance value for search results by taking the integral of the curve across the time interval that the user has specified, or again adjusting the transparency of images representing these forms.

Conclusion

As noted above, the highly quantitative nature of this model does not bring any more certainty, nor does it address all of the concerns raised at the start of this paper. However, it does seem to promise a more intuitive and meaningful way of interacting with the content. It has been observed that the computer should not be used to provide firm answers or proving the truth of hypotheses regarding historical fact, but should instead provide means for interaction, visualisation and knowledge creation (Clement et al. 2009; Jessop 2008; Sculley and Pasanek 2008). Paradoxically, then, the benefit of the model proposed here could lie not in its mathematical accuracy but the opposite: by highlighting the ‘fuzziness’ of the content it may help to break down the illusion of certainty that the computer typically brings, and may instead present a more useful and meaningful interface. Initial experiments and informal surveys with medievalists to date has suggested very strong support indeed for this approach. No doubt other, better models will be developed by others in due course, but the point remains for now that the representation of dates in databases of manuscripts and documents is too narrow, and more imagination is required if we are to make the best use of what we have.
